- DEX, ODEX
- APK
- Android's binary xml
- Android resources
- Disassemble DEX/ODEX bytecodes
- Decompiler for DEX/ODEX files

You can either use the cli or graphical frontend for androguard, or use androguard purely as a library for your own tools and scripts.

### 1.1 Introduction

#### 1.1.1 Installation

There are several ways how to install androguard.

##### Debian / Ubuntu

Debian has androguard in its repository. You can just install it using `apt install androguard`. All required dependencies are automatically installed.

##### Install from Source

Use git to fetch the sources, then install it. Please install git and python on your own. Beware, that androguard requires python 2.7 or at least 3.3 to work. Pypy >= 5.9.0 should work as well but is not tested. On Windows, there might be some issues with the magic library. Usually the Anaconda suite works fine!

```
git clone --recursive https://github.com/androguard/androguard.git
cd androguard
pip install .[magic]
```

if you like to install the GUI as well, use

```
pip install .[magic,GUI,graphing]
```

The dependencies, defined in `setup.py` will be automatically installed.

If you are installing the libraries using pip, make sure you download the correct packages. For example, there are a lot of implementations of the `magic` library. Get the one, that is shipped with the `file` command (See [Fine Free File Command](<http://www.darwinsky.com/file/>) or use `filenmagic`, which should work as well.

## 1.1.2 Getting Started

The easiest way to analyze APK files, is by using `androlyze.py`. It will start a iPython shell and has all modules loaded to get into action.

Open a terminal and type `androlyze.py -s`.

For analyzing and loading APK or DEX files, some wrapper functions exists. Use `AnalyzeAPK(filename)` or `AnalyzeDEX(filename)` to load a file and start analyzing:

```
a, d, dx = AnalyzeAPK("/home/user/some-app.apk")
```

The three objects you get are a an `androguard.core.bytecodes.apk.APK` object, d an array of `androguard.core.bytecodes.dvm.DalvikVMFormat` object and dx an `androguard.core.analysis.analysis.Analysis` object.

Inside the APK object, you can find all information about the APK, like package name, permissions, the AndroidManifest.xml or its resources.

The `androguard.core.bytecodes.dvm.DalvikVMFormat` corresponds to the DEX file found inside the APK file. You can get classes, methods or strings from the DEX file.

The `androguard.core.analysis.analysis.Analysis` object contains special classes, which link information about the classes.dex.

## Python API

---

### 2.1 androguard package

#### 2.1.1 Subpackages

`androguard.core` package

Subpackages

`androguard.core.analysis` package

The analysis module implements an abstraction layer for `androguard.core.bytecodes.dvm.DalvikVMFormat` objects. With the help of the `androguard.core.analysis.Analysis` object, you can bundle several DEX files together. This is not only useful for multidex files, but also for a single dex, as Analysis offers many features to investigate DEX files. One of these features is crossreferencing (XREF). It allows you to build a graph of the methods inside the DEX files. You can then create callgraphs or find methods which use a specific API method.

## androguard.core.bytecodes package

The bytecodes modules are one very important core feature of Androguard. They contain parsers for APK, AXML, DEX, ODEX and DEY files as well for formats used inside these formats. These might be MUTF-8 for string encoding in DEX files as well as the widely used LEB128 encoding for numbers.

The most important modules might be `androguard.core.bytecodes.apk.APK` and `androguard.core.bytecodes.dvm.DalvikVMFormat`.

**Return type** a list with all strings used in the format (types, names ...)

**get\_strings\_unicode()**

Return all strings

This method will return pure UTF-16 strings. This is the “exact” same string as used in Java. Those strings can be problematic for python, as they can contain surrogates as well as “broken” surrogate pairs, ie single high or low surrogates. Such a string can for example not be printed. To avoid such problems, there is an escape mechanism to detect such lonely surrogates and escape them in the string. Of course, this results in a different string than in the Java Source!

Use `get_strings()` as a general purpose and `get_strings_unicode()` if you require the exact string from the Java Source. You can always escape the string from `get_strings_unicode()` using the function `androguard.core.bytecodes.mutf8.patch_string(s)`.

**androguard.decompiler.dad.control\_flow module**

androguard.decompiler.dad.control\_flow.**catch\_struct** (graph, idoms)  
 androguard.decompiler.dad.control\_flow.**derived\_sequence** (graph)  
     Compute the derived sequence of the graph G The intervals of G are collapsed into nodes, intervals of these nodes are built, and the process is repeated iteratively until we obtain a single node (if the graph is not irreducible)  
 androguard.decompiler.dad.control\_flow.**identify\_structures** (graph, idoms)  
 androguard.decompiler.dad.control\_flow.**if\_struct** (graph, idoms)  
 androguard.decompiler.dad.control\_flow.**intervals** (graph)  
     Compute the intervals of the graph Returns interval\_graph: a graph of the intervals of G interv\_heads: a dict of (header node, interval)  
 androguard.decompiler.dad.control\_flow.**loop\_follow** (start, end, nodes\_in\_loop)

     Bases: object  
     **run** ()  
**class** androguard.decompiler.dad.dataflow.**DummyNode** (name)  
     Bases: *androguard.decompiler.dad.node.Node*  
     **get\_loc\_with\_ins** ()  
 androguard.decompiler.dad.dataflow.**build\_def\_use** (graph, lparams)  
     Builds the Def-Use and Use-Def (DU/UD) chains of the variables of the method.  
 androguard.decompiler.dad.dataflow.**clear\_path** (graph, reg, loc1, loc2)  
     Check that the path from loc1 to loc2 is clear. We have to check that there is no side effect between the two location points. We also have to check that the variable *reg* is not redefined along one of the possible paths from loc1 to loc2.  
 androguard.decompiler.dad.dataflow.**clear\_path\_node** (graph, reg, loc1, loc2)  
 androguard.decompiler.dad.dataflow.**dead\_code\_elimination** (graph, du, ud)  
     Run a dead code elimination pass. Instructions are checked to be dead. If it is the case, we remove them and we update the DU & UD chains of its variables to check for further dead instructions.

```
androguard.decompiler.dad.dataflow.group_variables (lvars, DU, UD)
androguard.decompiler.dad.dataflow.place_declarations (graph, dvars, du, ud)
androguard.decompiler.dad.dataflow.reach_def_analysis (graph, lparams)
androguard.decompiler.dad.dataflow.register_propagation (graph, du, ud)
```

Propagate the temporary registers between instructions and remove them if necessary. We process the nodes of the graph in reverse post order. For each instruction in the node, we look at the variables that it uses. For each of these variables we look where it is defined and if we can replace it with its definition. We have to be careful to the side effects some instructions may have. To do the propagation, we use the computed DU and UD chains.

```
androguard.decompiler.dad.dataflow.split_variables (graph, lvars, DU, UD)
```

```
androguard.decompiler.dad.dataflow.update_chain (graph, loc, du, ud)
```

Updates the DU chain of the instruction located at loc such that there is no more reference to it so that we can remove it. When an instruction is found to be dead (i.e it has no side effect, and the register defined is not used) we have to update the DU chain of all the variables that may be used by the dead instruction.

androguard.decompiler.dad.graph.make_node (graph, block, block_to_node, vmap, gen_ret)
```

```
androguard.decompiler.dad.graph.simplify(graph)
```

Simplify the CFG by merging/deleting statement nodes when possible: If statement B follows statement A and if B has no other predecessor besides A, then we can merge A and B into a new statement node. We also remove nodes which do nothing except redirecting the control flow (nodes which only contains a goto).

```
androguard.decompiler.dad.graph.split_if_nodes(graph)

Split IfNodes in two nodes, the first node is the header node, the second one is only composed of the jump condition.

## androguard.decompiler.dad.util module

```
androguard.decompiler.dad.util.build_path(graph, node1, node2, path=None)
```

Build the path from node1 to node2. The path is composed of all the nodes between node1 and node2, node1 excluded. Although if there is a loop starting from node1, it will be included in the path.

```
androguard.decompiler.dad.util.common_dom(idom, cur, pred)
```

```
androguard.decompiler.dad.util.create_png(cls_name, meth_name, graph,
                                              dir_name='graphs2')

```

```
androguard.decompiler.dad.util.get_access_method(access)
```

```
androguard.decompiler.dad.util.get_params_type(descriptor)
```

Return the parameters type of a descriptor (e.g (IC)V)

```
androguard.decompiler.dad.util.get_type(atype, size=None)
```

Retrieve the java type of a descriptor (e.g : I)

```
androguard.decompiler.dad.util.get_type_size(param)
```

Return the number of register needed by the type @param

```
androguard.decompiler.dad.util.merge_inner(clsdict)
```

Merge the inner class(es) of a class: e.g class A { ... } class A\$foo{ ... } class A\$bar{ ... } ==> class A { class foo{...} class bar{...} ... }
